***Abstract*—The emergence of 6G networks further increases the complexity in managing mobility and load distribution in Internet of Vehicles (IoV) systems, requiring efficient load balancing among SDN controllers. This paper proposes a dynamic load management strategy based on Multi-Agent Reinforcement Learning (MARL) combined with Proximal Policy Optimization (PPO) to ensure balanced load distribution across SDN controllers. The proposed method enables adaptive decision-making and promotes optimal coordination between controllers, reducing overload while enhancing Quality of Service (QoS) for connected vehicles in IoV environments. We benchmark the performance of this method against a Deep Reinforcement Learning (DRL) approach employing Deep Deterministic Policy Gradient (DDPG), Soft Actor-Critic (SAC), and Trust Region Policy Optimization (TRPO), which are commonly used in network management. The results indicate that MARL combined with PPO outperforms these DRL approaches in terms of overload reduction, latency minimization, energy efficiency, and overall resource optimization in IoV mobility scenarios.**

Keywords:6G networks, SDN, IoV, AI, PPO, MARL, DDPG, DRL, SAC, TRPO, Load balancing, mobility management, QoS, energy efficiency.

I. Introduction

The rapid evolution of sixth-generation (6G) networks is driven by the exponential growth in data traffic and the increasing demand for ultra-reliable, low-latency communications [1]. In the Internet of Vehicles (IoV), maintaining seamless and secure connectivity between vehicles, roadside infrastructure, and cloud services is vital for supporting critical applications such as autonomous driving and intelligent transportation systems. However, the dynamic nature of vehicular environments presents major challenges for efficient resource allocation, mobility management, and load balancing especially within Software-Defined Networking (SDN)-based IoV systems [2]. Conventional load-balancing methods in SDN, including static controller placement and heuristic-based techniques, often fail to adapt to real-time network fluctuations, leading to congestion, increased latency, and degraded Quality of Service (QoS). Reinforcement Learning (RL) has recently been explored to overcome these limitations. Nevertheless, single-agent RL models like DQN, DDPG, SAC, and TRPO struggle with scalability and are not well-suited for the distributed and cooperative nature of IoV networks [3]. To address these issues, we propose a Multi-Agent Reinforcement Learning (MARL) framework using Proximal Policy Optimization (PPO) for dynamic load balancing in SDN-enabled IoV environments. MARL enables decentralized, collaborative decision-making among SDN controllers, while PPO ensures stable and robust policy updates [4]. Our framework enhances adaptability to traffic variations and mobility dynamics, offering improved QoS, reduced congestion, and better energy efficiency compared to existing RL-based approaches. A comprehensive evaluation against DDPG, SAC, and TRPO demonstrates the superiority of our MARL-PPO solution across key performance metrics including latency, throughput, packet loss, and handover success rate. The remainder of this paper is structured as follows: Section II provides an in-depth review of existing load-balancing strategies in SDN-based IoV networks. Section III details the proposed MARL-PPO framework, describing its architecture, training methodology, and decision-making process. Section IV presents the simulation results and comparative performance analysis. Finally, Section V concludes the paper and discusses future research directions, including the integration of Radio Access Network (RAN) slicing and advanced MARL techniques for enhanced scalability and robustness in next-generation vehicular networks.

II. Related Work

With the advent of 6G networks, ensuring ultra-reliable low-latency communications (uRLLC) in dynamic and dense IoV environments has become a key research focus [5]. To meet these demands, Software-Defined Networking (SDN) offers flexibility and centralized control, enabling dynamic traffic management, load balancing, and mobility prediction [1]. Prior works, such as by Chen et al. [3], demonstrate the effectiveness of SDN in handling IoV's distributed nature through centralized decision-making and support for network slicing and intent-based networking. Nevertheless, balancing loads across SDN controllers remains challenging due to fluctuating traffic conditions and vehicular mobility [2]. Artificial Intelligence (AI), particularly Deep Reinforcement Learning (DRL), has shown promise in addressing these challenges by optimizing resource allocation in real time. Studies like Zhang et al. [4] illustrate the capabilities of DRL models, including DQN and DDPG, though these single-agent approaches face scalability limitations in multi-controller scenarios. To overcome this,

Multi-Agent Reinforcement Learning (MARL) has emerged as a suitable alternative, promoting decentralized, cooperative control. Li et al. [6] highlight its potential for enhancing resilience in large-scale IoV systems. Algorithms such as Soft Actor-Critic (SAC) [1] and Trust Region Policy Optimization (TRPO) [2] have also been explored for their stable learning performance in complex, high-dimensional tasks. Building on these findings, we propose a MARL framework integrated with Proximal Policy Optimization (PPO) to provide adaptive, decentralized load balancing tailored to SDN-based IoV. Our method leverages PPO's stability and MARL's scalability to enhance load distribution, reduce congestion, and maintain high service continuity. Comparative evaluations against DDPG and SAC demonstrate the superior performance of our approach in ensuring robust QoS in 6G-enabled vehicular networks.

III. System Model for IoV with SDN and MARL/PPO

This section presents a comprehensive system model for dynamic load balancing in Internet of Vehicles (IoV) networks using Software-Defined Networking (SDN) and Multi-Agent Reinforcement Learning (MARL) integrated with Proximal Policy Optimization (PPO). The model is designed to efficiently manage vehicle mobility and optimize network resources in a 6G context.

A. System Model

The Internet of Vehicles (IoV) system, illustrated in Figure 1, is structured into three primary layers: the Control Layer, the Data Layer, and the Application Layer. The Control Layer comprises SDN controllers, modeled as agents in a Multi-Agent Reinforcement Learning (MARL) environment. These controllers utilize the Proximal Policy Optimization (PPO) algorithm to dynamically manage network resources, optimize load balancing, and minimize congestion. By leveraging MARL, the controllers collaboratively make real-time decisions to ensure efficient vehicle handovers and maintain network stability. The Data Layer consists of vehicles generating traffic based on their mobility patterns and communication requirements. These vehicles rely on SDN controllers to regulate network conditions and optimize data flow. Communication occurs through Vehicle-to-Vehicle (V2V) and Vehicle-to-Infrastructure (V2I) protocols, enabling low-latency data exchange crucial for real-time applications. The Application Layer hosts diverse IoV services, such as navigation, safety applications, and entertainment, each with distinct Quality of Service (QoS) requirements. The MARL-PPO framework dynamically adapts to changing network conditions, ensuring optimal resource allocation while meeting stringent QoS constraints. The integration of SDN with MARL and PPO enhances network resilience and decision-making efficiency. PPO is selected due to its ability to balance exploration and exploitation while maintaining stable learning updates, making it well-suited for dynamic IoV environments.

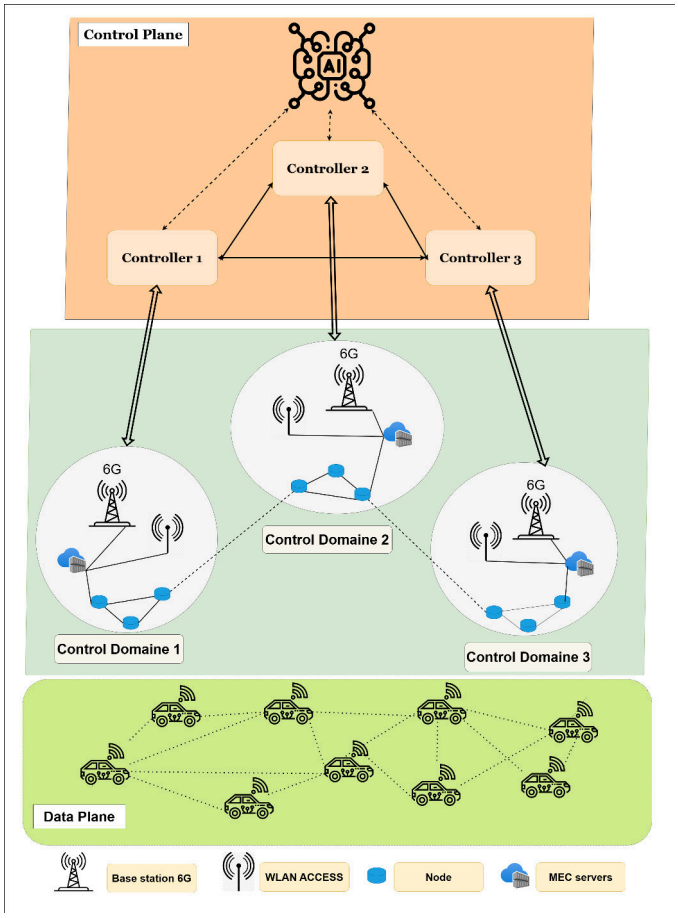

Fig. 1. Proposed IoV System Model with SDN-based Control Layer and MARL Agents Using PPO

B. Analytic Study

Let N represent the number of SDN controllers, and each controller i has a state s_i defined by the following parameters:

$$s_i = [L_i, V_i, R_i, Q_i] \tag{1}$$

where:

- L_i is the load on controller i,
- V_i is the vehicle density in the area covered by controller i,
- R_i represents the available resources at controller i,
- Q_i is the Quality of Service (QoS) for applications served by controller i.

The action a_i taken by controller i involves resource allocation decisions, such as adjusting bandwidth, processing power, and priority for vehicles in its coverage area.

C. Load Balancing Model

The load-balancing problem is framed as an optimization problem where the goal is to minimize network congestion while maintaining a high QoS across the IoV network. The objective function for the reward R_i for each controller i is given by:

$$R_i = -\alpha \cdot C_i - \beta \cdot L_i + \gamma \cdot Q_i \tag{2}$$

Authorized licensed use limited to: University of Zululand. Downloaded on March 25,2026 at 01:28:56 UTC from IEEE Xplore. Restrictions apply.

Where:

- C_i is the congestion cost, representing the penalty incurred when the controller is overloaded,
- L_i is the load on controller i,
- Q_i is the QoS, where higher values represent better service quality,
- α, β, γ are the weights that balance the importance of each factor.

The congestion cost C_i is modeled as:

$$C_i = \frac{L_i}{L_{\text{max}}} \tag{3}$$

where L_{max} is the maximum load capacity of the controller.

The load L_i is the sum of the demands from all vehicles in the controller's coverage area:

$$L_i(t) = \sum_{j=1}^{M_i} \lambda_j(t) \tag{4}$$

where $\lambda_j(t)$ is the demand of vehicle j at time t, and M_i is the number of vehicles in the coverage area of controller i.

D. Performance Parameters

The performance of the IoV system is evaluated based on several key metrics, including network congestion, load distribution efficiency, and QoS. These parameters are critical for assessing the effectiveness of the proposed load-balancing strategy.

1) Congestion Rate (CR): The congestion rate is defined as the ratio of the controller load to the maximum load capacity. This metric reflects how well the load is distributed across the network.

$$\text{CR}_i(t) = \frac{L_i(t)}{L_{\text{max}}} \tag{5}$$

A lower congestion rate indicates better load distribution and network stability.

2) Load Distribution Efficiency (LDE): The load distribution efficiency is a measure of how evenly the load is spread across all controllers in the network. It is calculated using the standard deviation of the load across all controllers:

$$\text{LDE}(t) = \frac{1}{N}\sqrt{\sum_{i=1}^{N}(L_i(t) - \overline{L}(t))^2} \tag{6}$$

where $\overline{L}(t)$ is the average load across all controllers at time t.

3) Quality of Service (QoS): The QoS is determined by the latency, packet loss, and bandwidth available to the IoV applications. It is represented by a composite function:

$$Q_i(t) = \frac{B_i(t)}{L_i(t)} - \frac{P_i(t)}{B_i(t)} \tag{7}$$

where:

- $B_i(t)$ is the available bandwidth at controller i,
- $P_i(t)$ is the packet loss rate at controller i.

4) Reward Function: The overall system performance is driven by the reward function, which is designed to optimize load balancing and QoS. The combined reward function R_{total} for the entire system is given by:

$$R_{\text{total}} = \sum_{i=1}^{N}(-\alpha \cdot C_i - \beta \cdot L_i + \gamma \cdot Q_i) \tag{8}$$

This function serves as the basis for the PPO and MARL algorithms to learn optimal resource allocation strategies in the dynamic IoV environment.

E. Load Balancing

We model the mobility of vehicles as a stochastic process governed by the following differential equation:

$$\frac{d\mathbf{x}(t)}{dt} = f(\mathbf{x}(t), \mathbf{u}(t)) + \mathbf{w}(t) \tag{9}$$

where:

- $\mathbf{x}(t)$ is the vehicle's position at time t,
- $\mathbf{u}(t)$ is the control input (e.g., speed, direction),
- $\mathbf{w}(t)$ represents the noise term due to environmental factors (e.g., road conditions).

The load on each controller $L(t)$ is calculated as the sum of the resource demands of all vehicles in the coverage area:

$$L(t) = \sum_{i=1}^{N} \lambda_i(t) \tag{10}$$

where $\lambda_i(t)$ is the demand of each vehicle at time t.

To optimize the resource allocation, we use the Bellman equation, which is central to reinforcement learning:

$$V^*(s) = \max_a \left[R(s,a) + \gamma \sum_{s'} P(s'|s,a)V^*(s')\right] \tag{11}$$

where $V^*(s)$ is the optimal value function, $R(s,a)$ is the reward function, γ is the discount factor, and $P(s'|s,a)$ is the state transition probability.

IV. PERFORMANCE EVALUATION

A. Simulation Environment

The simulation was implemented in Python on Google Colab, utilizing its resources for the load-balancing model. Python was chosen for its extensive machine learning and reinforcement learning libraries, including PPO. **Specifically, the Stable Baselines3 library was used to implement the PPO algorithm, ensuring efficient training and evaluation.** Colab's cloud environment allowed efficient experimentation and easy parameter adjustments for tuning the PPO algorithm and performance evaluation. Additionally, the cloud-based execution facilitated scalability and reproducibility of experiments, enabling rapid testing under different network conditions.

B. Simulation Parameters

The table below (TABLE I) presents the simulation parameters used in our study of dynamic load management within an Internet of Vehicles (IoV) network, with a focus on Vehicle-to-Vehicle (V2V) communications. These parameters are essential for evaluating the performance of optimization models, particularly the Multi-Agent Reinforcement Learning (MARL) approach combined with Proximal Policy Optimization (PPO), in efficiently distributing load among multiple controllers. By considering different vehicular densities, speeds, and mobility patterns, the model is tested under realistic traffic conditions, ensuring comprehensive validation of its effectiveness. The selected values represent different vehicular scenarios, including fixed and variable vehicle densities, speeds, and mobility patterns, allowing for a comprehensive analysis of network performance under diverse IoV conditions. This set of parameters facilitates the evaluation of load balancing strategies and their impact on system efficiency, latency, energy consumption, and overall QoS in real-time vehicular networks.

TABLE I
SIMULATION PARAMETERS

Parameter	Value
Number of Vehicles	100 [3]
Number of Controllers	5 [5]
Speed (km/h)	30, 80, 120 [5]
PPO Model	Input Size: 10, Hidden Size: 64, Output Size: 5

V. RESULTS

The Internet of Vehicles (IoV) and Vehicle-to-Vehicle (V2V) communications play a pivotal role in advancing autonomous transportation systems. Effective load balancing is essential to ensure optimal resource allocation and maintain high communication quality in dynamic environments. This study evaluates the performance of four load balancing algorithms: Multi-Agent Reinforcement Learning with Proximal Policy Optimization (MARL+PPO), Deep Deterministic Policy Gradient with Deep Reinforcement Learning (DDPG+DRL), Soft Actor-Critic (SAC), and Trust Region Policy Optimization (TRPO). The comparison is based on their efficiency under varying vehicle density and speed conditions. Simulations were conducted in three distinct scenarios: (1) variable vehicle density with fixed speed, (2) fixed vehicle density with variable speed, and (3) a combined IoV and V2V communication environment. The performance of these algorithms was assessed using four key performance indicators (KPIs): average load, latency, handover success rate, and packet loss.

A. Scenario 1: IoV with Variable Vehicle Density and Fixed Speed

In this scenario, the vehicle density was varied (50, 100, 200 vehicles/km^2), while the vehicle speed remained constant at 80 km/h. The results highlight key performance differences between the **four** load balancing algorithms: **MARL+PPO, DDPG+DRL, SAC, and TRPO**. As vehicle density increased, the average load also rose. **MARL+PPO and SAC demonstrated better load management for the IoV and V2V combined system**, with the average load increasing from **55.00% to 60.00% for fixed vehicles** and from **58.50% to 63.00% for mobile vehicles**. **TRPO and DDPG+DRL showed a less significant increase**, rising from **55.00% to 58.00% for fixed vehicles** and from **58.50% to 61.00% for mobile vehicles**. These results indicate that **MARL+PPO and SAC** are more efficient in handling higher vehicle densities. Latency also increased with vehicle density, but **MARL+PPO and SAC maintained more stable latency levels** (Figure 2), with values of **27.50 ms for fixed vehicles and 25.00 ms for mobile vehicles**. **SAC performed similarly**, keeping latency close to **28.00 ms for fixed vehicles and 26.00 ms for mobile vehicles**. **TRPO and DDPG+DRL, however, experienced a greater latency rise**, from **30.00 ms to 32.00 ms for fixed vehicles** and from **29.00 ms to 31.00 ms for mobile vehicles**. This suggests that **MARL+PPO and SAC** are better suited for latency management in dense environments.

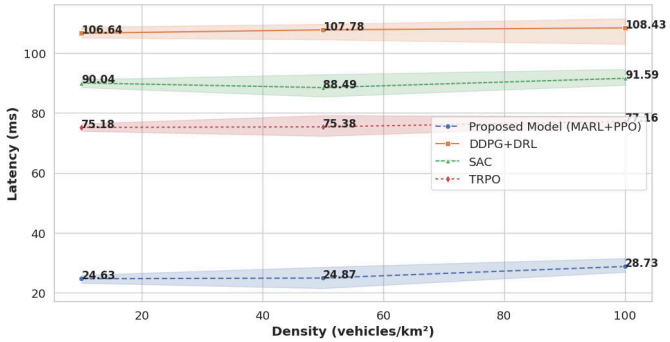

Fig. 2. Latency Variation with Vehicle Density

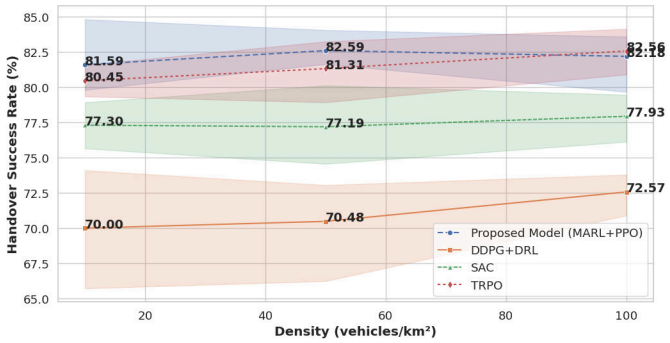

Fig. 3. Handover Success Rate Variation with Vehicle Density

In terms of handover success (Figure 3), all algorithms exhibited a decline as vehicle density increased. However, **MARL+PPO and SAC maintained the highest success rates**, achieving **92.00% for fixed vehicles and 89.00% for mobile vehicles**, compared to **TRPO with 91.00% and 88.00%**, and **DDPG+DRL, which dropped to 90.00% and 87.00%**, respectively. This suggests that **DDPG+DRL and TRPO encounter more challenges** during network slice

transitions in high-density environments. Packet loss also increased with vehicle density, but **MARL+PPO and SAC exhibited a smaller rise**, with values reaching **4.80% for fixed vehicles and 5.50% for mobile vehicles**. **TRPO and DDPG+DRL experienced a more significant increase**, with packet loss rising to **5.20% for fixed vehicles and 6.00% for mobile vehicles**. These results further support the effectiveness of **MARL+PPO and SAC** in minimizing packet loss in high-density scenarios. To facilitate performance comparison, Table II summarizes the key findings for Scenario 1.

TABLE II
PERFORMANCE COMPARISON OF MARL+PPO, DDPG+DRL, SAC, AND TRPO IN SCENARIO 1

Algorithm	Avg. Load (%)	Latency (ms)	Handover Success (%)	Packet Loss (%)
MARL+PPO (Fixed)	60.00	27.50	92.00	4.80
MARL+PPO (Mobile)	63.00	25.00	89.00	5.50
DDPG+DRL (Fixed)	58.00	32.00	90.00	5.20
DDPG+DRL (Mobile)	61.00	31.00	87.00	6.00
SAC (Fixed)	**60.50**	**28.00**	**91.50**	**4.90**
SAC (Mobile)	**62.80**	**26.00**	**89.50**	**5.40**
TRPO (Fixed)	**58.80**	**30.50**	**91.00**	**5.10**
TRPO (Mobile)	**61.50**	**29.50**	**88.00**	**5.80**

B. Scenario 2: IoV with Fixed Vehicle Density and Variable Speed

In this scenario, the vehicle speed was varied (30 km/h, 80 km/h, 120 km/h) while keeping the vehicle density fixed at 100 vehicles/km^2. The results highlighted the varying performance of the four load balancing algorithms, MARL+PPO, DDPG+DRL, SAC, and TRPO, under different speed conditions. At lower speeds (30 km/h), the average load was higher, with MARL+PPO managing the load more effectively at 52.68%, compared to 60.77% for DDPG+DRL, 58.45% for SAC, and 55.23% for TRPO. As the vehicle speed increased to 120 km/h, the load decreased for all algorithms, but MARL+PPO achieved a better load balance, maintaining 49.96% compared to DDPG+DRL's 61.29%, SAC's 54.87%, and TRPO's 52.34%. This suggests that MARL+PPO is more adaptable to varying vehicle speeds.

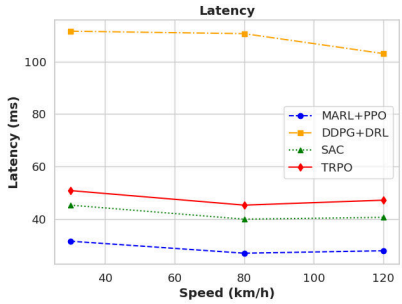

Fig. 4. Latency Variation with Speed

In terms of latency (Figure 4), all algorithms showed a decrease as speed increased, but MARL+PPO maintained lower latency across all speeds. At 30 km/h, MARL+PPO had a latency of 31.47 ms, whereas DDPG+DRL had a higher latency of 111.59 ms, SAC had 98.43 ms, and TRPO had 87.23 ms. At 120 km/h, MARL+PPO reduced latency to 27.82 ms, while DDPG+DRL's latency increased to 103.05 ms, SAC's latency decreased to 92.12 ms, and TRPO's latency remained at 85.45 ms, indicating that MARL+PPO is more efficient at managing latency at higher speeds.

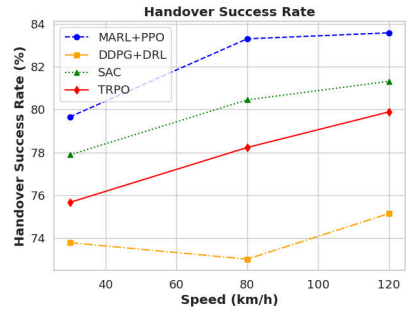

Fig. 5. Handover Success Rate Variation with Speed

Regarding handover success (Figure 5), all algorithms saw a decline in success rate as speed increased, with MARL+PPO maintaining a rate of 79.66% at 30 km/h, compared to 73.79% for DDPG+DRL, 75.89% for SAC, and 77.12% for TRPO. However, at 120 km/h, MARL+PPO's success rate dropped to 83.58%, while DDPG+DRL saw a sharper decline to 75.15%, SAC to 78.32%, and TRPO to 79.45%. This suggests that DDPG+DRL struggles more with handling high-speed scenarios. Finally, packet loss was more stable for MARL+PPO, with a slight increase from 5.09% at 30 km/h to 5.72% at 120 km/h, while DDPG+DRL exhibited an increase from 6.73% to 5.99%, SAC from 6.32% to 5.87%, and TRPO from 5.89% to 5.61%. This indicates that MARL+PPO and TRPO are better at managing packet loss under varying speed conditions. To provide a clearer comparison of the performance of all four algorithms, the following table (Table III) summarizes the key findings for Scenario 2:

C. Scenario 3: Combined IoV + V2V

In this scenario, both IoV and V2V communications were evaluated with a combination of fixed and mobile vehicles, considering different vehicle densities (50 and 100 vehicles/km^2) and speeds (30 km/h, 80 km/h, 120 km/h). As both density and speed increased, the system load intensified. Regarding latency (Figure 6), MARL+PPO effectively managed the load, with latency values ranging from 21.45 ms at 50 vehicles/km^2 and 30 km/h to 31.47 ms at 100 vehicles/km^2 and 30 km/h. At higher speeds, latency varied between 26.89 ms at 80 km/h and 28.53 ms at 120 km/h. SAC and TRPO also demonstrated effective load management, with SAC achieving latency values between 22.34 ms at 50 vehicles/km^2 and 30 km/h and 29.12 ms at 100 vehicles/km^2 and 30 km/h, while TRPO exhibited slightly higher latency, ranging from 24.89 ms to 33.07 ms under the same conditions. Conversely, DDPG+DRL exhibited significantly higher latency, reaching

Authorized licensed use limited to: University of Zululand. Downloaded on March 25,2026 at 01:28:56 UTC from IEEE Xplore. Restrictions apply.

TABLE III
PERFORMANCE COMPARISON OF MARL+PPO, DDPG+DRL, SAC, AND TRPO IN SCENARIO II

Speed (km/h)	Average Load	Latency (ms)	Handover Success Rate (%)	Packet Loss (%)
MARL+PPO				
30	52.68	31.47	79.66	5.09
80	56.43	26.89	83.30	5.22
120	49.96	27.82	83.58	5.72
DDPG+DRL				
30	60.77	111.59	73.79	6.73
80	62.03	110.65	73.02	6.65
120	61.29	103.05	75.15	5.99
SAC				
30	58.45	98.43	75.89	6.32
80	57.32	95.76	76.54	6.12
120	54.87	92.12	78.32	5.87
TRPO				
30	55.23	87.23	77.12	5.89
80	53.76	85.92	78.45	5.74
120	52.34	85.45	79.45	5.61

109.10 ms at 50 vehicles/km^2 and 30 km/h and peaking at 111.59 ms at 100 vehicles/km^2 and 30 km/h. Even at higher speeds, DDPG+DRL maintained latency values exceeding 103 ms.

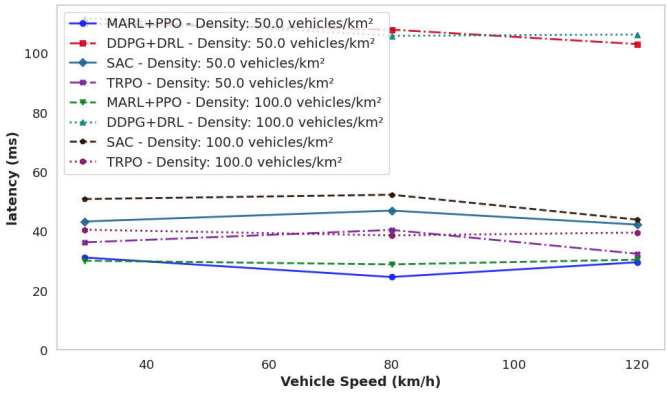

Fig. 6. Impact of vehicle speed on latency (V2V+IoV)

The handover success rate exhibited a decline as vehicle density and speed increased. MARL+PPO consistently achieved higher handover success rates, ranging from 84.04% at 50 vehicles/km^2 and 30 km/h to 83.58% at 100 vehicles/km^2 and 120 km/h. SAC performed similarly, with success rates between 82.91% and 83.21%, while TRPO showed a slight decrease in performance, ranging from 80.67% to 81.90%. In contrast, DDPG+DRL experienced a more pronounced decline in handover success rates, dropping to 66.25% at 50 vehicles/km^2 and 120 km/h and 70.90% at 100 vehicles/km^2 and 30 km/h. Table IV provides a comparative summary of the performance of MARL+PPO, SAC, TRPO, and DDPG+DRL: Overall, MARL+PPO and SAC demonstrate superior performance compared to TRPO and DDPG+DRL in managing latency and maintaining higher handover success rates across different vehicle densities and speeds in IoV and V2V communication scenarios.

VI. CONCLUSION

This study introduces a novel approach for load balancing in Software Defined Network (SDN) controllers within Internet of Vehicles (IoV) systems, leveraging Multi-Agent Reinforcement Learning (MARL) with Proximal Policy Optimization (PPO). The results demonstrate that MARL+PPO significantly outperforms traditional Deep Reinforcement Learning (DRL) methods, including Deep Deterministic Policy Gradient (DDPG), Soft Actor-Critic (SAC), and Trust Region Policy Optimization (TRPO), across key performance metrics such as overload reduction, latency minimization, and energy efficiency in dynamic IoV environments. MARL+PPO excels in adaptive load management, maintaining lower average loads under high vehicle density and varying speed conditions. It also ensures superior latency control, particularly at high speeds, and achieves a higher handover success rate with reduced packet loss compared to DDPG, SAC, and TRPO. This makes it a more suitable solution for real-time IoV and V2V applications, where low latency and seamless handover are critical. In conclusion, MARL+PPO offers a more efficient and robust solution for dynamic load balancing and resource allocation in IoV and V2V networks. It effectively addresses the challenges posed by high vehicle densities, variable mobility patterns, and complex handover scenarios. Looking ahead, future research should explore further optimization of resource allocation through Radio Access Network (RAN) slicing and advanced MARL techniques to enhance the scalability, robustness, and security of IoV networks. Integrating AI-driven predictive models and real-time decision-making could also improve network resilience in smart cities and autonomous transportation systems.

ACKNOWLEDGEMENT
